

Purpose of Investigation and Procedures

Facial recognition is the product of specialized neural mechanisms. Previous research suggests that the fusiform face area (FFA) in the human extrastriate cortex is specifically tuned to the recognition of faces (Kanwisher, 1997). Facial identification is also a feature- and identity-based process that involves multiple neural regions. In an attempt to model the mechanisms involved in facial recognition, Valentine (1991) proposed a framework in which a specific point in multidimensional space represented a unique facial identity. This “face space” includes a neutral or general face at its center with unique faces surrounding the center like spokes on a wheel (Valentine, 1991). Leopold and colleagues (2001) found that if individuals adapted to a particular facial identity in this “face space,” their subsequent perception of neutral faces was altered in that faces previously judged to be neutral suddenly took on a new identity (i.e., the neutral face now looked like someone else), an effect that has been termed the “face aftereffect”. Interestingly, the effect was shown for inverted faces, which are known to be processed by different neural mechanisms in addition to the FFA. These findings emphasize a difference between facial identity and object recognition mechanisms that may work in parallel during the identification of inverted faces.

What is currently unknown is the extent to which facial aftereffects transfer to different orientations (e.g., inverted faces, or faces rotated to an intermediate orientation). Specifically, if a participant adapts to an upright face, with that adaptation transfer to a neutral face positioned at a different orientation. In the current study, participants will sit in front of a computer monitor and learn a set of four faces. They will then view one of those four faces during an adapting phase (4000 msec) in either an upright or inverted orientation. During the test phase, they will view one of the four previously learned faces for 200 msec and then make a forced-choice response concerning the identity of the face. In a between groups study, participants will either be assigned to the control or experimental condition. The control group will not contain an adapting component (i.e., test phase only). The experimental condition will contain both an adapting phase and a test phase. The duration of the experiment will take approximately 1 hr to complete.

Anticipated Risk and Potential Benefits to Participants

There are no potential benefits for the participants. While this is a low risk procedure, there is some potential risk. Participants may be uncomfortable while they are sitting in the chair and focusing on the computer screen display. However, this would be the same amount of risk or discomfort that a student would experience when sitting in front of a computer screen and typing a paper for about an hour. Participants will be given the option to take breaks between trials and to ask the experimenter to clarify any confusion. The experimenter will also make sure that the participants are seated a comfortable distance from the computer screen and that they fully understand the task.

Steps Taken to Protect the Participants

Steps will be taken to protect the confidentiality of the participants. Participants will be asked to sign the Certificate of Informed Consent before beginning the experiment. Data obtained in the experiment will not be linked to any identifying information regarding the identity of the participants. All participants will be allowed to withdraw from the experiment at any time and still receive course credit if they are a PSYC 150 student.

Manner of Obtaining Participants

Everyone in the Psychology 150 class will be eligible to participate in this study, as well as any other interested Colgate students, faculty, or staff. Psychology 150 students will receive 1 hr of participation credit for participating in the experiment, and the experimenter will sign their cards after completion of the experimental task. All of the participants will read and sign the Certificate of Informed Consent before beginning the experiment. Upon completion of the experiment, participants will be verbally debriefed regarding the aim of the study.

Certificate of Informed Consent

Overview and Procedure. This is a study on visual perception and facial recognition. Participants will be asked to make decisions on four previously learned facial identities viewed at varying orientations on a computer monitor. Participants will sit in front of a computer screen and learn the identities of four faces. They will then view one of those four faces during an adapting phase (4000 msec) in either an upright or inverted orientation. During the test phase, they will view one of the four previously learned faces for 200 msec and then make a forced-choice response concerning the identity of the face. The procedure should take approximately 1 hour.

Risk and Benefits. There are no direct benefits to you as a participant. While this is a low risk procedure, there is some potential risk. The primary risk is associated with ergonomics. You will be required to remain seated in front of a computer display during the experiment, and this may cause a low level of discomfort. If you do become uncomfortable, you will be able take short breaks in between experimental trials, which are about 6 minutes each. If you are not willing to accept these risks, please inform the experimenter and withdraw from the experiment.

Confidentiality. Your privacy will be protected. At no time will identifying information be attached to your responses. Any information obtained during the course of this experiment will remain confidential and will be used solely for research purposes. Within these restrictions, results of this study will be made available to you upon request.

Compensation. If you are a PSYC 150 student, you will receive one research credit for participation in this study.

Your Rights. Your participation in this study is voluntary. You may withdraw from this study at any time and still receive research credit if you are a PSYC 150 student.

Contact Information. If you have questions or concerns about your rights as a participant, please contact the principal investigator of this project, XXX, her faculty supervisor, XXX, or the Chair of the IRB committee at Colgate University, IRB_chair@psych.colgate.edu.

By signing below, you are agreeing 1) to participate in this study, and 2) that you have read and understand all of the information provided on this form.
